## COMPRESSIBLE LAMINAR BOUNDARY LAYER OVER A YAWED INFINITE CYLINDER WITH HEAT TRANSFER AND ARBITRARY PRANDTL NUMBER<sup>1,2</sup>

By ELI RESHOTKO and IVAN E. BECKWITH

### SUMMARY

The equations are presented for the development of the compressible laminar boundary layer over a yawed infinite cylinder. For compressible flow with a pressure gradient the chordwise and spanwise flows are not independent. Using the Stewartson transformation and a linear viscosity-temperature relation yields a set of three simultaneous ordinary differential equations in a form yielding similar solutions. These equations are solved for stagnation-line flow for surface temperatures from zero to twice the free-stream stagnation temperature and for a wide range of yaw angle and free-stream Mach number.

The results indicate that the effect of yaw on the heat-transfer coefficient at the stagnation line depends markedly on the free-stream Mach number. For subsonic Mach numbers the decrease in heat-transfer coefficient with yaw angle  $\Delta$  is about  $\sqrt{\cos \Delta}$ , which is the decrease for incompressible flow. However, for free-stream Mach numbers greater than approximately 2, the variation in heat-transfer coefficient with yaw angle is somewhat less than  $\cos \Delta$  except when the normal component of the stream Mach number is subsonic; then the variation tends to approach  $\sqrt{\cos \Delta}$ . This decrease in heat-transfer coefficient with yaw angle is practically independent of wall temperature and Prandtl number for the values of these parameters used in the present calculations. The recovery factor, defined in terms of the local external temperature, can be approximated as the square root of the Prandtl number for the range of yaw angle, Mach number, and Prandtl number, included in the calculations.

An unusual result of the solutions is that for large yaw angles and stream Mach numbers the chordwise velocity within the boundary layer exceeds the local external chordwise velocity, even for a highly cooled wall.

### INTRODUCTION

As flight speeds are increased, the problem of aerodynamic heating becomes more serious, and the temperatures of critical areas such as the nose of an aircraft or the wing leading edge may exceed the design specifications. An accurate knowledge of the laminar-boundary-layer characteristics then becomes desirable, not only for predicting heat-transfer rates, but also for calculating the stability of the boundary-layer flow. The yawed infinite cylinder approxi-

mately simulates the leading edge of a sweptback wing or of a body of high fineness ratio at angle of attack and also allows a basic simplification of the boundary-layer theory.

Almost simultaneously, Prandtl (ref. 2), Struminsky (ref. 3), Jones (ref. 4), and Sears (ref. 5) observed that for incompressible flow over a yawed infinite cylinder the boundary-layer development in the chordwise direction (normal to the cylinder axis) is independent of the spanwise flow. For compressible flow, however, this "independence principle" does not apply, because the density variation must depend on the velocities in both the chordwise direction and the spanwise direction (refs. 3 and 6).

Where the independence principle applies, the solutions for boundary-layer development in the chordwise plane are those that have been obtained for incompressible two-dimensional flow. A number of investigators have integrated the spanwise momentum equation for the various solutions to this problem. Sears (ref. 5) has obtained the spanwise solution corresponding to the series-type solution about a cylinder. Wild (ref. 7), by an integral technique, has obtained the spanwise solution for Howarth's elliptic cylinder, and Cooke (ref. 8) has tabulated the spanwise solutions corresponding to Hartree's solutions (ref. 9) to the equations of Falkner and Skan. Further, Goland (ref. 10) has shown that the heat-transfer coefficient of a yawed cylinder varies as the square root of the Reynolds number based on the normal component of the stream velocity. Thus, for a given stream velocity, the heat-transfer coefficient decreases as the square root of the cosine of the yaw angle. This decrease in heat-transfer coefficient is associated with the increase in boundary-layer thickness due to yaw.

For compressible flow where the independence principle does not apply, the momentum equations for both the chordwise flow and the spanwise flow must be solved simultaneously. Solutions to the compressible-flow problem with zero heat transfer and a Prandtl number of 1 have been given by Crabtree (ref. 11) and Tinkler (ref. 12). Both of these solutions are for flows where the spanwise Mach number at the stagnation line of the cylinder is 1 or less. Consequently, for high stream Mach numbers these solutions apply only to cases where the yaw angle is small. From the

<sup>1</sup> Supersedes NACA Technical Note 3936, by Eli Reshotko and Ivan E. Beckwith, 1957.

<sup>2</sup> This report combines the results of two independent investigations, one at the Lewis Flight Propulsion Laboratory and the other at the Langley Aeronautical Laboratory. The principal results of the investigation at the Lewis laboratory were presented by the senior author before the 1956 Heat Transfer and Fluid Mechanics Institute at Stanford University on June 22, 1956. A brief written version of that talk appears in the proceedings of the institute (ref. 1).

observation that for a Prandtl number of 1 the energy equation and the spanwise momentum equations are similar (ref. 6), Moore (ref. 13) has indicated the form that Crabtree's equations take for a noninsulated surface.

The present report extends the work of Crabtree, Tinkler, and Moore to the more general case of arbitrary Prandtl number and an isothermal wall at arbitrary temperature in flows where both Mach number and yaw angle may be large. The boundary-layer equations are first simplified by the assumption of a linear viscosity-temperature relation and by the application of Stewartson's transformation (ref. 14). The resulting system of partial differential equations is simplified further by assuming an external chordwise velocity distribution of the Falkner-Skan type in the transformed coordinate system. The conditions required to reduce the system to ordinary differential equations are discussed. Numerical solutions for stagnation-line flow with Prandtl numbers of 1 and 0.7 are presented. Expressions are given for shear, heat transfer, and the variation of heat-transfer coefficient with yaw angle.

#### GENERAL EQUATIONS

##### BOUNDARY-LAYER EQUATIONS

The compressible-boundary-layer equations for a three-dimensional flow are obtained by application of the Prandtl boundary-layer assumptions to the general equations governing the motion of a compressible, viscous, heat-conducting gas (see, e. g., refs. 6 and 13). One of these assumptions which may be emphasized for the present application is that the boundary-layer thickness is small compared with the local radius of curvature of the surface. Consequently, the pressure gradient normal to the surface may be neglected, and the boundary-layer equations are expected to be valid in the region of the stagnation line on a yawed cylinder.

The boundary-layer equations for a yawed infinite cylinder are obtained from the three-dimensional boundary-layer equations by noting that all spanwise derivatives are identically zero. The coordinate system used is defined by the following sketch:

where the  $x$ -coordinate is the distance along the cylinder surface measured in the chordwise direction from the leading-edge stagnation line,  $y$  is the spanwise coordinate, and  $z$  is the coordinate normal to the cylinder surface. (All symbols are defined in appendix A.)

The equations of motion of the steady compressible laminar boundary layer over a yawed infinite cylinder are therefore: Continuity:

$$\frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho w)}{\partial z} = 0 \quad (1)$$

Momentum:

$$\rho u \frac{\partial u}{\partial x} + \rho w \frac{\partial u}{\partial z} = -\frac{\partial p}{\partial x} + \frac{\partial}{\partial z} \left( \mu \frac{\partial u}{\partial z} \right) \quad (2a)$$

$$\rho u \frac{\partial v}{\partial x} + \rho w \frac{\partial v}{\partial z} = \frac{\partial}{\partial z} \left( \mu \frac{\partial v}{\partial z} \right) \quad (2b)$$

$$\frac{\partial p}{\partial z} = 0 \quad (2c)$$

Energy:

$$\rho u \frac{\partial H}{\partial x} + \rho w \frac{\partial H}{\partial z} = \frac{\partial}{\partial z} \left( \frac{\mu}{Pr} \frac{\partial H}{\partial z} \right) - \frac{\partial}{\partial z} \left[ \mu \left( \frac{1}{Pr} - 1 \right) \frac{\partial}{\partial z} \left( \frac{u^2 + v^2}{2} \right) \right] \quad (3)$$

where  $H$  is the total or stagnation enthalpy.

State:

$$p = \rho R t$$

The boundary conditions for equations (1) to (4) are:  
At  $z=0$

$$u=v=w=0 \text{ and } H=H_w \text{ or } \frac{\partial H}{\partial z}=0$$

At  $z \rightarrow \infty$

$$u=u_s, v=v_s, \text{ and } H=H_s$$

The viscosity is assumed to be a linear function of the temperature according to the relation

$$\mu = \frac{\mu_w}{t_w} t$$

where  $t_w$  is a known function of  $x$ , and  $\mu_w$  may be taken as any desired function of  $t_w$ , such as the Sutherland viscosity-temperature equation. The chordwise velocity outside the boundary layer satisfies the following form of Bernoulli's equation:

$$\rho_s u_s \frac{du_e}{dx} = -\frac{dp_e}{dx} = -\frac{\partial p}{\partial x} \quad (5)$$

since from equation (2c) the pressure is constant in the direction normal to the surface.

#### STEWARTSON'S TRANSFORMATION

The velocities in the equations of motion (eqs. (1) to (3)) can be replaced through the definition of a stream function:

$$\left. \begin{aligned} \psi_z &\equiv \frac{\rho u}{\rho_0} \\ \psi_x &\equiv -\frac{\rho w}{\rho_0} \end{aligned} \right\} \quad (6)$$

so that the continuity equation (eq. (1)) is automatically satisfied.

Stewartson's transformation (ref. 14) is now introduced, and in a slightly modified form may be written

$$X = \int_0^x \left( \frac{\mu_w}{\mu_0} \frac{t_0}{t_w} \right) \frac{a_e}{a_0} \frac{p_e}{p_0} dx \quad (7)$$

$$Z = \frac{a_e}{a_0} \int_0^z \frac{p}{p_0} dz \quad (8)$$

The quantity  $\left( \frac{\mu_w}{\mu_0} \frac{t_0}{t_w} \right)$  of equation (7) is exactly the quantity  $\lambda$  of reference 15. The transformed coordinates are now represented by uppercase letters ( $X, Z$ ), and the subscript  $e$  refers to local conditions at the outer edge of the boundary layer (external). The subscript 0 refers to free-stream stagnation values.

With the assumptions of constant Prandtl number, constant specific heat, and an isothermal surface and by use of the adiabatic energy equation for the external flow

$$a_0^2 = a_e^2 + \frac{\gamma-1}{2} (v_e^2 + v_z^2) \quad (9)$$

equations (2a), (2b), and (3) become

$$\begin{aligned} \psi_z \psi_{xz} - \psi_x \psi_{zz} &= U_e U_{ex} \left[ 1 + \left( \frac{t_0}{t_{N_0}} - 1 \right) (1 - g^2) + \right. \\ &\quad \left. \left( \frac{t_w}{t_0} - 1 \right) \left( \frac{t_0}{t_{N_0}} \right) (1 - \theta) \right] + v_0 \psi_{zzz} \end{aligned} \quad (10)$$

$$\psi_z g_x - \psi_x g_z = v_0 g_{zz} \quad (11)$$

$$\begin{aligned} \psi_z \theta_x - \psi_x \theta_z &= -\frac{v_0}{Pr} \frac{(1-Pr)(\gamma-1)}{2a_0^2} \left[ \left( \frac{a_e}{a_0} \right)^2 (\psi_z)_{zz} + v_e^2 (g^2)_{zz} \right] + \\ &\quad \frac{v_0}{Pr} \theta_{zz} \end{aligned} \quad (12)$$

where

$$g = \frac{v}{v_e} \quad (13)$$

$$\theta = \frac{H - H_w}{H_e - H_w} \quad (14)$$

and

$$\frac{t_0}{t_{N_0}} = \frac{1 + \frac{\gamma-1}{2} M_\infty^2}{1 + \frac{\gamma-1}{2} M_\infty^2 \cos^2 \Lambda} \quad (15)$$

The ratio  $t_0/t_{N_0}$  combines the effect of both yaw angle and Mach number in a single parameter. The physical interpretation of this parameter is simply the ratio of the total or stagnation temperature of the stream to the stagnation temperature of the normal component of the stream. The variation of the parameter with yaw angle for various Mach numbers is shown in figure 1. It is seen that  $t_0/t_{N_0} \leq \sec^2 \Lambda$  and becomes large only for large yaw angles combined with high Mach numbers.

FIGURE 1.—Effect of yaw angle on yaw parameter. Ratio of specific heats, 1.4.

For a Prandtl number of 1,  $g = \theta$ , since equations (11) and (12) are similar and since the functions  $g$  and  $\theta$  satisfy the same boundary conditions.

In terms of the transformed velocities, which are defined

$$\begin{cases} U = \psi_z \\ W = -\psi_x \end{cases} \quad (16)$$

equations (10) to (12) can be written

$$\begin{aligned} UU_x + WU_z &= U_e U_{ex} \left[ 1 + \left( \frac{t_0}{t_{N_0}} - 1 \right) (1 - g^2) + \right. \\ &\quad \left. \left( \frac{t_w}{t_0} - 1 \right) \frac{t_0}{t_{N_0}} (1 - \theta) \right] + v_0 U_{zz} \end{aligned} \quad (17)$$

$$UG_x + WG_z = v_0 g_{zz} \quad (18)$$

$$\begin{aligned} U\theta_x + W\theta_z &= \frac{v_0}{Pr} \left\{ \theta_{zz} - \left( \frac{\gamma-1}{2a_0^2} \right) \left( \frac{1-Pr}{1-\frac{t_w}{t_0}} \right) \left[ \left( \frac{a_e}{a_0} \right)^2 (U^2)_{zz} + \right. \right. \\ &\quad \left. \left. v_e^2 (g^2)_{zz} \right] \right\} \end{aligned} \quad (19)$$

These equations should be useful in formulating integral methods for calculation of laminar boundary layers over yawed cylinders.

#### SIMILAR SOLUTIONS

In order to obtain similar solutions, an external flow of the Falkner-Skan type

$$U_e = CX^\alpha \quad (20)$$

is assumed, which together with the transformation

$$\left. \begin{array}{l} \psi = f(\eta) \sqrt{\frac{2\nu_0 U_e X}{m+1}} \\ g = g(\eta) \\ \theta = \theta(\eta) \\ \eta = Z \sqrt{\frac{m+1}{2} \frac{U_e}{\nu_0 X}} \end{array} \right\} \quad (21)$$

yields the system of differential equations

$$f''' + ff'' = \beta \left[ f'^2 - 1 - \left( \frac{t_0}{t_{N_0}} - 1 \right) (1 - g^2) - \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) (1 - \theta) \right] \quad (22a)$$

$$g'' + fg' = 0 \quad (22b)$$

$$\theta'' + Pr f \theta' = \frac{1 - Pr}{\left( 1 - \frac{t_w}{t_0} \right)} \left[ \frac{\gamma - 1}{2} \left( \frac{u_e}{a_0} \right)^2 (f'^2)'' + \left( 1 - \frac{t_{N_0}}{t_0} \right) (g^2)'' \right] \quad (22c)$$

where

$$\beta = \frac{2m}{m+1} \quad (23)$$

The boundary conditions for the system of equations (22) are:

At  $\eta=0$

$$\left. \begin{array}{l} f = f' = g = \theta = 0 \\ f' = g = \theta = 1 \end{array} \right\} \quad (24)$$

Since  $u_e$  may in general depend on  $x$ , the right member of the energy equation (eq. (22c)) is not yet functionally consistent with the left member for arbitrary  $u_e$  and  $Pr$ . The right member of the equation must be zero or a function of  $\eta$  to be consistent with the left member. This may be achieved in the following ways: (1) The external chordwise velocity may be a constant other than zero, (2) the external chordwise velocity may be zero, (3) the Prandtl number may equal 1, (4) the factor  $\left[ \frac{\gamma - 1}{2} \left( \frac{u_e}{a_0} \right)^2 \right]$  may approach the constant  $t_{N_0}/t_0 = \cos^2 \Lambda$  corresponding to hypersonic flow, or (5) the ratio of specific heats  $\gamma$  may equal 1.

#### INDEPENDENCE PRINCIPLE

The independence principle can be demonstrated from the general system of equations (22). The chordwise momentum equation (eq. (22a)) is independent of the spanwise momentum and energy equations under the following conditions:

- (1) Flat-plate flows ( $m=\beta=0$ ) for all Mach numbers, Prandtl numbers, and heat transfers
- (2) The conditions  $t_0=t_{N_0}$ ,  $t_w=t_0$ , which correspond to incompressible flow

Independence does not exist for compressible flow with pressure gradient, even for zero heat transfer.

#### STAGNATION-LINE FLOW

All solutions presented in this report are for stagnation-line flow where  $m=\beta=1$ . Two of the previously described requirements for similarity are separately considered in these solutions. The first requirement is that of Prandtl number equal to 1. The system of equations (22) for this case is reduced to the following two differential equations, since equations (22b) and (22c) become identical:

$$f''' + ff'' = f'^2 - 1 - \left( \frac{t_0}{t_{N_0}} - 1 \right) (1 - g^2) - \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) (1 - \theta) \quad (25a)$$

$$\theta'' + f\theta' = 0 \quad (25b)$$

with the boundary conditions:

At  $\eta=0$

$$\left. \begin{array}{l} f = f' = \theta = 0 \\ f' = \theta = 1 \end{array} \right\} \quad (26)$$

For the case of zero yaw, equations (25) reduce to those presented in reference 15, while for the insulated surface ( $\frac{t_w}{t_0} = 1$  for  $Pr=1$ ) they reduce to those of Crabtree (ref. 11).

The second requirement considered is that of zero external chordwise velocity, which allows arbitrary Prandtl number. For this case equations (22) become

$$f''' + ff'' = f'^2 - 1 - \left( \frac{t_0}{t_{N_0}} - 1 \right) (1 - g^2) - \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) (1 - \theta) \quad (27a)$$

$$g'' + fg' = 0 \quad (27b)$$

$$\theta'' + Pr f \theta' = (1 - Pr) \frac{\frac{t_{N_0}}{t_0}}{1 - \frac{t_w}{t_0}} (g^2)'' \quad (27c)$$

With heat transfer, the boundary conditions of equations (27) are equations (24).

For the case of the insulated wall an additional boundary condition is necessary, since the wall temperature is no longer arbitrary. The heat-transfer rate to the wall may be expressed as

$$q_w = k_w \left( \frac{\partial t}{\partial z} \right)_w \quad (28)$$

which for stagnation-line flow becomes, with use of expressions (8), (14), and (21),

$$q_w = \frac{\rho_w}{\rho_0} \frac{a_e}{a_0} \sqrt{\frac{C}{\nu_0}} k_w (t_0 - t_w) \theta'_w \quad (29)$$

For the insulated surface,  $q_w=0$ ; and since with arbitrary Prandtl number the surface temperature is generally not equal to the stagnation temperature, the additional boundary condition from equation (29) is

$$\theta'_w = 0 \quad (30)$$

Thus, for the insulated surface with arbitrary Prandtl number, equations (27) are solved subject to the conditions of equations (24) and (30). For convenience in computing, the temperature ratio  $t_w/t_0$  was replaced by the following expression involving the local recovery factor  $\xi_w$ :

$$\frac{t_w}{t_0} = \frac{t_{aw}}{t_0} = \xi_w \left( 1 - \frac{t_{N_0}}{t_0} \right) + \frac{t_{N_0}}{t_0} \quad (31)$$

Values of  $\xi_w$  then resulted from the solutions.

Equations (25) and (27) were solved numerically for both insulated and noninsulated surfaces. The techniques used at the two laboratories were different. These techniques are discussed in appendix B. It is interesting and gratifying to note that the different techniques yielded numerical results that were in excellent agreement.

### PROPERTIES OF SOLUTIONS

In the following sections the solutions obtained in this study are presented and their properties discussed. All solutions are presented in tabular form. Table I shows the values of  $f$ ,  $f'$ ,  $f''$ ,  $\theta$ , and  $\theta'$  tabulated against  $\eta$  for a Prandtl number of 1. Table II presents  $f$ ,  $f'$ ,  $f''$ ,  $g$ ,  $g'$ ,  $\theta$ , and  $\theta'$  against  $\eta$  for a Prandtl number of 0.7. Table III presents a summary of the values of  $f''_w$  (related to wall shear),  $g'_w$  (related to spanwise shear), and  $\theta'_w$  (related to heat transfer) for the cases of tables I and II.<sup>3</sup> The solutions for  $Pr=1.0$  apply whenever the external chordwise velocity satisfies equation (20) with  $m=1$ ; whereas, the solutions for  $Pr \neq 1.0$  apply rigorously only at the stagnation line where  $u_e=0$ . For practical purposes, however, the solutions for  $Pr \neq 1.0$  are expected to apply also in the vicinity of the stagnation line where  $u_e \ll a_0$ .

### VELOCITY AND ENTHALPY PROFILES

The chordwise and spanwise velocity and enthalpy profiles obtained from the tabulated solutions are presented as functions of  $\eta$  in figures 2 and 3.

The chordwise velocity ratio can be expressed

$$\frac{u}{u_e} = f' \quad (32)$$

from the definitions of  $\psi$ ,  $z$ , and  $\eta$ . It should be remembered that for the  $Pr=1$  solutions the normalized temperature and spanwise velocity profiles are identical. For  $Pr=0.7$  (fig. 3) the spanwise velocity and enthalpy profiles are separately plotted. The distance  $z$  normal to the surface at a given station  $x$  in the physical plane is related to the similarity variable  $\eta$  through relations (8) and (21) and may be expressed as

$$z = \frac{a_0 p_0}{a_e p_e} \sqrt{\frac{v_0 X}{U_e}} \left( \frac{2}{m+1} \right) \int_0^\eta \frac{t}{t_0} d\eta \quad (33)$$

where

$$\frac{t}{t_0} = 1 + \left( \frac{t_w}{t_0} - 1 \right) (1 - \theta) - \frac{\gamma - 1}{2} \left( \frac{u_e}{a_0} \right)^2 f'^2 - \left( 1 - \frac{t_{N_0}}{t_0} \right) g^2 \quad (34)$$

At the stagnation line, equations (33) and (34) become

$$z = \frac{t_0}{t_w} \sqrt{\frac{v_0}{\left( \frac{du_e}{dx} \right)}} \int_0^\eta \left[ 1 + \left( \frac{t_w}{t_0} - 1 \right) (1 - \theta) - \left( 1 - \frac{t_{N_0}}{t_0} \right) g^2 \right] d\eta \quad (35)$$

The differences in the profiles for different values of the yaw-angle parameter  $t_0/t_{N_0}$  and the wall-temperature parameter  $t_w/t_0$  (fig. 2) can be attributed to the effect of compressibility, since for incompressible flow the chordwise velocity profiles and the temperature profiles are independent of the spanwise flow. The chordwise velocity ratios are especially affected by compressibility; for large values of  $t_0/t_{N_0}$  these ratios are greater than 1 within the boundary layer, even for cases where the wall is highly cooled. This same phenomenon has been observed in solutions of the two-dimensional compressible boundary layer (e.g., refs. 15 and 16) for cases of a heated wall and favorable pressure gradient, and in reference 15 was termed "velocity overshoot." According to reference 15, the physical explanation for this effect is: When the wall is heated, the density in the outer part of the boundary layer is reduced sufficiently so that the local flow is accelerated more than the external flow. The same basic explanation appears plausible in the present solutions, except that the additional heat required to reduce the local density is generated by the shear of the spanwise boundary layer, and, hence, the phenomenon can occur even when the wall temperature is less than the recovery temperature. The solutions given by Moore for the compressible-boundary-layer equations for a cone at large angle of attack (ref. 17) also show similar results; that is, the circumferential velocity ratios are greater than unity within the boundary layer. Furthermore, this effect becomes larger as the angle of attack of the cone is reduced.<sup>4</sup> In the present solutions this is analogous to increasing the yaw angle, which also has the effect of increasing the excess of the local velocities over the external velocity. Note also that this excess chordwise velocity is reduced by reducing the wall temperature, as might be expected from the preceding discussion.

Twelve solutions were computed with  $Pr=0.7$ ; four of these are for zero heat transfer and give a recovery factor, and eight are for cooled-wall conditions with  $t_w/t_0=0$  and 0.5. The velocity and enthalpy profiles for these solutions are shown in figure 3, and the numerical values of the functions are given in tables II and III. For corresponding values of  $t_0/t_{N_0}$  and for  $t_w/t_0=0$  or 0.5, the  $f'$ ,  $g$ , and  $\theta$  profiles are almost the same as those for  $Pr=1$ . For  $t_w=t_{aw}$ , the  $f'$  and  $g$  profiles are also similar to those for  $Pr=1$  with  $t_w=t_0$ ; however, the  $\theta$  profiles for  $Pr=0.7$  and  $t_w=t_{aw}$  (fig. 3(a)) are considerably different from the corresponding profiles for  $Pr=1$ . The fact that  $\theta > 1$  for this case indicates that the local stagnation enthalpy within the boundary layer exceeds the stagnation enthalpy outside the boundary layer. This excess of local stagnation enthalpy over the external value

<sup>3</sup> Comparison of the results of reference 11 with the solution given here for  $Pr=1$ ,  $t_w/t_0=1$ ,  $t_0/t_{N_0}=1.2$  shows that the present values for  $f'$  and  $\theta$  (corresponding to  $f_1+f_2$  and  $g_1+g_2$  in the notation of ref. 11) are considerably larger than the values given in reference 11 at the same  $\eta$ . According to private communication with Dr. Crabtree, the original numerical results of reference 11 were in error. The corrected results obtained from Dr. Crabtree, also by private communication, are in substantial agreement with the present solution.

<sup>4</sup> The angle of yaw as defined herein is the complement of the cone angle of attack.

for zero heat transfer (and also to a lesser extent for a cooled wall) is apparently caused by the relative increase in the quantity of heat conducted away from the wall into the outer layers of the boundary layer when  $Pr < 1$ . For  $Pr = 1$  and zero heat transfer ( $t_w = t_0$ ) the relative effects of viscosity and conductivity are balanced and  $H/H_e = 1$  throughout the boundary layer. These same effects have been previously noted in solutions of the flat-plate boundary layer (e. g., ref. 18).

The domains of velocity and temperature overshoot can be identified with the aid of the asymptotic solution to equations (27) (appendix C). For simplicity, the discussion that follows is restricted to a Prandtl number of 1. A more general treatment is given in appendix C.

The asymptotic expressions for chordwise and spanwise velocity functions for a Prandtl number of 1 from appendix C are, respectively,

$$\tilde{f}' = 1 + \frac{A_1}{4} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right] (\eta - \kappa)^{-1} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] + A_3 (\eta - \kappa)^{-3} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] \quad (36)$$

and

$$\tilde{g} = 1 - \frac{A_1}{2} (\eta - \kappa)^{-1} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] \quad (37)$$

Examination of equation (36) shows that for large  $\eta$  the term involving  $A_1$  is dominant, and thus  $(f' - 1)$  will have the

(d) Wall-temperature ratio, 2.0.

FIGURE 2.—Concluded. Velocity and enthalpy profiles for Prandtl number of 1.

same sign as  $A_1$ . Since the  $g$  function for a Prandtl number of 1 (fig. 2) always approaches its boundary condition from below,  $A_1$  is always positive, and, consequently, the existence of chordwise velocity overshoot depends directly on whether the quantity  $\left[2\left(\frac{t_0}{t_{N_0}}-1\right)+\frac{t_0}{t_{N_0}}\left(\frac{t_w}{t_0}-1\right)\right]$  is positive.

This quantity is positive when  $t_w+t_0 > 2t_{N_0}$ . The domain of chordwise velocity overshoot is shown in figure 4. It may be seen that for cold surfaces there is only a small range of  $t_0/t_{N_0}$  in which no overshoot occurs.

For Prandtl numbers other than 1, the behavior of the stagnation-temperature profile must be considered separately from the spanwise velocity profile. From appendix C the asymptotic variation of  $\theta$  is

$$\tilde{\theta} = 1 + A_1 \frac{\left(1 - \frac{t_{N_0}}{t_0}\right)}{\left(\frac{t_w}{t_0} - 1\right)} (\eta - \kappa)^{-1} \exp\left[-\frac{(\eta - \kappa)^2}{2}\right] -$$

(d)

$$\frac{A_1}{2} \left[ \frac{2\left(1 - \frac{t_{N_0}}{t_0}\right) + \frac{t_w}{t_0} - 1}{\frac{t_w}{t_0} - 1} \right] (\eta - \kappa)^{-1} \exp\left[-\frac{Pr(\eta - \kappa)^2}{2}\right] \quad (38)$$

Figure 3 indicates that even for a Prandtl number of 0.7 the obtained spanwise velocity profiles approach the boundary condition from below; hence,  $A_1$  is positive from equation (37). For Prandtl numbers less than 1 the dominant term in equation (38) is the last one; thus the existence of temperature overshoot is dependent on whether the quantity

$$\left[ \frac{2\left(1 - \frac{t_{N_0}}{t_0}\right) + \frac{t_w}{t_0} - 1}{\frac{t_w}{t_0} - 1} \right]$$

is negative. The quantity is negative when the numerator is positive with  $t_w/t_0 < 1$ . It must, of course, be realized that for  $t_w/t_0 > 1$  the stagnation temperatures in the boundary layer are always higher than the stream stagnation temperature. In appendix C it is shown

(a) Spanwise velocity and enthalpy function.

FIGURE 3.—Velocity and enthalpy profiles for Prandtl number of 0.7.

FIGURE 3.—Concluded. Velocity and enthalpy profiles for Prandtl number of 0.7.

that the chordwise velocity overshoot domain for a Prandtl number of 0.7 is the same as for a Prandtl number of 1. Thus for a cold wall with  $Pr=0.7$ , velocity overshoot and enthalpy overshoot occur simultaneously. The various regions of overshoot are summarized in figure 4.

FIGURE 4.—Domains of velocity and enthalpy overshoot for stagnation-line flow over yawed cylinder.

#### SKIN FRICTION

The chordwise and spanwise components of shear stress at the wall are defined, respectively, as

$$\tau_c \equiv \mu_w \left( \frac{\partial u}{\partial z} \right)_w = \mu_w u_w f''_w \sqrt{\frac{U_e}{\nu_0 X} \frac{m+1}{2} \frac{\rho_w a_e}{\rho_0 a_0}} \quad (39)$$

$$\tau_s \equiv \mu_w \left( \frac{\partial v}{\partial x} \right)_w = \mu_w v_w g'_w \sqrt{\frac{U_e}{\nu_0 X} \frac{m+1}{2} \frac{\rho_w a_e}{\rho_0 a_0}} \quad (40)$$

These can be represented in dimensionless form by local skin-friction coefficients:

$$\frac{\tau_c}{\frac{1}{2} \rho_w U_e^2} \sqrt{\frac{u_e x}{\nu_w}} = 2 f''_w \sqrt{\frac{m+1}{2} \frac{d \ln X}{d \ln x}} \quad (41)$$

$$\frac{\tau_s}{\frac{1}{2} \rho_w v_e^2} \sqrt{\frac{v_e x}{\nu_w}} = 2 \sqrt{\frac{u_e}{\nu_e}} g'_w \sqrt{\frac{m+1}{2} \frac{d \ln X}{d \ln x}} \quad (42)$$

For the specific case of stagnation-line flow  $U_e = CX$  the quantity  $C$  is related to the physical chordwise velocity gradient as follows:

$$C = \frac{U_e}{X} = \frac{dU_e}{dX} = \left[ \frac{1 + \frac{\gamma - 1}{2} \left( \frac{u_e}{a_e} \right)^2}{\frac{\mu_w t_0}{\mu_0 t_w} \left( \frac{a_e}{a_0} \right) \frac{p_e}{p_0}} \right] \frac{du_e}{dx} \quad (43)$$

By use of equation (43), equations (39) and (40) can then be written in the form of skin-friction coefficients based on free-stream conditions, which for stagnation-line flow are

$$c_{f,c} = \frac{\tau_c}{\frac{1}{2} \rho_\infty (u_\infty^2 + v_\infty^2)} = 2 f_w'' \frac{\rho_\infty}{\rho_\infty u_\infty^2} \frac{u_e}{u_\infty^2} \cos^2 \Delta \left\{ \left[ 1 + \frac{\gamma-1}{2} \left( \frac{u_e}{a_e} \right)^2 \right] v_w \frac{du_e}{dx} \right\}^{\frac{1}{2}} \quad (44)$$

$$c_{f,s} = \frac{\tau_s}{\frac{1}{2} \rho_\infty (u_\infty^2 + v_\infty^2)} = g_w' \frac{\rho_\infty}{\rho_\infty} \frac{\sin 2\Delta}{u_\infty} \left\{ \left[ 1 + \frac{\gamma-1}{2} \left( \frac{u_e}{a_e} \right)^2 \right] v_w \frac{du_e}{dx} \right\}^{\frac{1}{2}} \quad (45)$$

At the stagnation line itself, the chordwise velocity in the boundary layer is identically zero; hence, there is zero chordwise viscous shearing stress. The dimensionless wall-shear function  $f_w''$  is nevertheless of interest, since it can be used in calculating  $c_{f,c}$  from equation (44) in the region close to the stagnation line. For the presented solutions, values of  $f_w''$  are summarized in table III and plotted in figure 5. Significant increases in the wall-shear function occur with increases in the yaw parameter  $t_0/t_{N_0}$ . This is an indication of the effect of lack of independence between the spanwise and chordwise flows.

In the evaluation of the spanwise skin-friction coefficient for a Prandtl number of 1, the function  $g_w'$  is exactly  $\theta_w'$ , as

FIGURE 5.—Effect of yaw on wall-shear function for stagnation-line flow.

indicated in table III and in figure 6. For a Prandtl number of 0.7, the values of  $g_w'$  for the obtained solutions are listed in table III. It may be readily seen from the table that for corresponding values of surface temperature and yaw parameter  $t_0/t_{N_0}$ , there is very little effect of Prandtl number on the spanwise shear parameter  $g_w'$ .

FIGURE 6.—Effect of yaw on heat-transfer parameter for stagnation-line flow. (For Prandtl number of 1, spanwise shear parameter  $g_w'$  is equal to heat-transfer parameter  $\theta_w'$ .)

#### SECONDARY FLOW

Secondary flows are generally present in boundary layers whenever the direction of the pressure gradient impressed by the free-stream flow is different from the external flow direction. A comparison of the directions of the surface streamline and a corresponding streamline in the external flow provides a measure of the degree of secondary flow in the boundary layer.

The direction  $\alpha$  of the streamline in the vicinity of the surface is given by the expression

$$\tan \alpha_w = \frac{\left( \frac{\partial u}{\partial z} \right)_w}{\left( \frac{\partial v}{\partial z} \right)_w} = \frac{\tau_c}{\tau_s} = \frac{u_e f_w''}{v_e g_w'} \quad (46)$$

and the direction of the external streamline is

$$\tan \alpha_e = \frac{u_e}{v_e} \quad (47)$$

The ratio

$$\frac{\tan \alpha_w}{\tan \alpha_e} = \frac{f_w''}{g_w'} \quad (48)$$

is then indicative of the degree of secondary flow in the boundary layer. The angles  $\alpha_s$  and  $\alpha_w$  are defined in the following sketch:

Values of the ratio  $f''_w/g'_w$  for the obtained solutions are given in table III and are also plotted in figure 7. As the yaw parameter is increased, large relative increases in the secondary flow are obtained.

FIGURE 7.—Ratio of chordwise to spanwise surface-shear parameters for stagnation-line flow. (For Prandtl number of 1,  $\frac{f'''_w}{g'_w} = \frac{f''_w}{\theta'_w}$ .)

#### HEAT TRANSFER AND ADIABATIC WALL TEMPERATURE

The heat-transfer coefficient is defined as  $h = \frac{q_w}{t_{aw} - t_w}$ , and by use of equations (7), (8), (21), and (28) may be written in the dimensionless form

$$\frac{Nu}{\sqrt{Re_w}} = \frac{hx}{k_w} \sqrt{\frac{v_w}{u_s x}} = \left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta'_w \sqrt{\frac{m+1}{2} \frac{d \ln X}{d \ln x}} \quad (49)$$

In terms of physical quantities, the heat-transfer coefficient for stagnation-line flow may be expressed as

$$h = \left[ \left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta'_w \right] \frac{k_w}{\sqrt{\nu_w}} \sqrt{\frac{du_s}{dx} \left[ 1 + \frac{\gamma-1}{2} \left( \frac{u_e}{a_e} \right)^2 \right]} \quad (50)$$

The pertinent parameter from the exact solution is the quantity  $\left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta'_w$ . For a Prandtl number of 1, where  $t_{aw} = t_0$ , this quantity reduces to just  $\theta'_w$ . However, for Prandtl numbers other than 1, the complete expression is necessary, and the adiabatic wall temperature is required.

The quantity  $\left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta'_w$  for stagnation-line flow is plotted in figure 6 for the present solutions. Figures 5 and 6 show that, while yaw tends to increase both the wall-shear and the heat-transfer functions, the magnitude of the effect on heat transfer is much smaller than the corresponding effect on wall shear. For example, for  $t_0/t_{N_0} \leq 2$  and  $\Lambda \leq 45^\circ$ , which from figure 1 includes all free-stream Mach numbers, the heat-transfer parameter is increased less than 13 percent over the value for  $t_0/t_{N_0} = 1$ . This indicates that, for many practical problems, the effects of lack of independence on heat transfer may not be of great significance.

A comparison of the solutions for  $Pr=0.7$  and  $Pr=1$  at  $t_w/t_0 = 0$  and 0.5 indicates that the effect of Prandtl number, on the heat-transfer parameter is essentially independent of the yaw parameter and can be approximately accounted for by the expression

$$\left[ \left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta'_w \right]_{Pr} = Pr^{0.48} (\theta'_w)_{Pr=1} \quad (51)$$

The factor  $Pr^{0.48}$  in equation (51) represents an approximate average of the effect of Prandtl number on heat transfer based on the presented exact solutions. This factor differs slightly from the expression  $Pr^{0.4}$  proposed by Squire (ref. 19) for the unyawed stagnation-point flow.

The adiabatic wall or recovery temperature at the stagnation line can be calculated from equation (31), where the quantity  $\xi_w$  is the local recovery factor defined by

$$\xi_w = \frac{t_{aw} - t_{N_0}}{t_0 - t_{N_0}} \quad (52)$$

Values of  $\xi_w$  have been calculated and are presented in table IV. The values for incompressible flow ( $t_0/t_{N_0} = 1$ ) have been calculated by the method described in appendix D, while those for  $t_0/t_{N_0} > 1$  and  $Pr = 0.7$  were obtained by solving equations (27) subject to the boundary conditions of equations (24) and (30), as described in the section Similar Solutions.

The results for  $t_0/t_{N_0} = 1$  may be closely represented by  $Pr^{0.48}$ , and for  $t_0/t_{N_0} > 1$  there is only a slight rise in recovery factor from the incompressible value. It is thus felt that the use of the conventional laminar recovery factor  $Pr^{1/2}$  would be adequate for most purposes.

The local recovery factor may be converted to a recovery factor  $\mathcal{R}$  based on free-stream temperature through the expression

$$\mathcal{R} = \frac{t_{aw} - t_\infty}{t_0 - t_\infty} = 1 - (1 - \xi_w) \sin^2 \Lambda \quad (53)$$

## REYNOLDS ANALOGY

From equations (41) and (49) a Reynolds analogy parameter between heat transfer and chordwise shear may be written

$$\frac{\left(\frac{\tau_c}{\frac{1}{2}\rho_w U_e^2}\right)\left(\frac{u_e x}{v_w}\right)}{\frac{hx}{k_w}} = \frac{2f_w''}{\left(\frac{t_0 - t_w}{t_{aw} - t_w}\right)\theta_w'} \quad (54)$$

For a Prandtl number of 1, this equation reduces to  $2f_w''/\theta_w'$ , which is just twice the secondary-flow parameter listed in table III and plotted in figure 7.

A more interesting and perhaps more useful Reynolds analogy can be written in terms of the spanwise shear. From equations (42), (49), and (51),

$$\frac{\left(\frac{\tau_c}{\frac{1}{2}\rho_w U_e^2}\right)\left(\frac{v_e x}{v_w}\right)}{\frac{hx}{k_w}} = \frac{2g_w'}{\left(\frac{t_0 - t_w}{t_{aw} - t_w}\right)\theta_w'} = \frac{2}{Pr^{0.46}} \quad (55)$$

This latter approximate relation applies to all the present solutions, since for a Prandtl number of 1,  $g_w' = \theta_w'$ ; and the results shown in table III indicate that  $(g_w')_{Pr=1}$  is approximately equal to  $(g_w')_{Pr=0.7}$ . The resemblance of equation (55) to the conventional flat-plate Reynolds analogy is due to the zero pressure gradient in the spanwise direction.

## BOUNDARY-LAYER THICKNESS

The boundary-layer thickness in the physical plane can be computed from equation (35). By definition of the boundary-layer thickness  $\delta$  as the value of  $z$  at which  $\theta = 0.9990$  (i. e.,  $\eta = \eta_\delta$ ), the expression for boundary-layer thickness for a Prandtl number of 1 becomes (from eq. (35))

$$\delta \sqrt{\frac{u_\infty}{\nu_w D} \left( \frac{D}{u_\infty} \frac{du_e}{dx} \right) \frac{t_w}{t_0}} = \int_0^\delta \left[ \left( 1 - \frac{t_w}{t_0} \right) \theta - \left( 1 - \frac{t_{N_0}}{t_0} \right) \theta^2 + \frac{t_w}{t_0} \right] d\eta \quad (56)$$

This expression has been evaluated for a range of values of  $t_w/t_0$ , and the results are shown in figure 8. The actual boundary-layer thickness may then be computed easily for any given combination of flow variables and wall temperature.

FIGURE 8.—Boundary-layer thickness at stagnation line of yawed cylinder. Prandtl number, 1.

## ENGINEERING HEAT-TRANSFER RELATIONS FOR STAGNATION-LINE FLOW

The local rate of heat transfer to the wall per unit wall area is calculated from the relation

$$q_w = h(t_{aw} - t_w) \quad (57)$$

which requires a knowledge of the heat-transfer coefficient  $h$  and the adiabatic wall temperature  $t_{aw}$ .

The adiabatic wall temperature at the stagnation line is obtained from equation (52) with the recovery factor evaluated from table IV.

The expression for heat-transfer coefficient is

$$h = \frac{k_w}{\sqrt{\nu_w}} \left[ \left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta_w' \right] \sqrt{\frac{du_e}{dx} \left[ 1 + \frac{\gamma - 1}{2} \left( \frac{u_e}{a_e} \right)^2 \right]} \quad (58)$$

To evaluate the heat-transfer coefficient  $h$  in the stagnation-line region of a given yawed cylinder, it is necessary to evaluate the fluid properties at the wall, the chordwise velocity gradient  $du_e/dx$  and the heat-transfer parameter  $\left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta_w'$ . The evaluation of these items with consideration of the effects of yaw is discussed in the following paragraphs.

## FLUID PROPERTIES AT THE WALL

The thermal conductivity and absolute viscosity can be considered as functions of temperature alone, but the density varies also with the pressure according to the equation of state. The static pressure is determined from the inviscid flow. When the chordwise component of the free-stream velocity is supersonic, the wall pressure at the stagnation line is that which would be sensed by a Pitot tube placed normal to the shock. This pressure is related to the free-stream static pressure by the expression

$$\frac{p_{w_{st}}}{p_\infty} = \left( \frac{\gamma + 1}{2} M_{N_\infty}^2 \right)^{\frac{\gamma}{\gamma - 1}} \left[ \frac{\gamma + 1}{2\gamma M_{N_\infty}^2 - (\gamma - 1)} \right]^{\frac{1}{\gamma - 1}} \quad (58)$$

(where  $M_{N_\infty} = M_\infty \cos \Lambda$ ). For subsonic chordwise flow

$$\frac{p_{w_{st}}}{p_\infty} = \left( 1 + \frac{\gamma - 1}{2} M_{N_\infty}^2 \right)^{\frac{\gamma}{\gamma - 1}} \quad (59)$$

## CHORDWISE VELOCITY GRADIENT

Based on the observation (refs. 20 and 21) that for normal circular cylinders at free-stream Mach numbers greater than 2 the pressure coefficient varies about the cylinder as

$$\frac{C_p}{C_{p,max}} \approx \cos^2 \left( \frac{2x}{D} \right) \quad (60)$$

an expression for the velocity gradient at the stagnation line  $du_e/dx$  was derived. This relation in dimensionless form is

$$\frac{D}{u_\infty} \left( \frac{du_e}{dx} \right) = \frac{2a_0}{M_\infty a_\infty} \sqrt{\frac{2}{\gamma} \left( 1 - \frac{p_\infty}{p_{w_{st}, \Lambda=0}} \right)} \quad (61)$$

Penland (ref. 20) further observed that equation (60) reasonably represents the chordwise pressure distribution over a yawed cylinder. Therefore, equation (61) for a yawed cylinder becomes just a function of the normal Mach number. With a normal Mach number greater than about 2 and upon introduction of the proper stagnation-line fluid properties, equation (61) becomes

$$\frac{D}{u_\infty} \frac{du_e}{dx} = \frac{2a_{N_0}}{a_\infty M_{N_\infty}} \sqrt{\frac{2}{\gamma} \left( 1 - \frac{p_\infty}{p_{w_{sl}, \Delta}} \right)} \quad (62)$$

It must be remembered that in equation (62)  $u_\infty$  is the chordwise component of the free-stream velocity.

For subsonic chordwise flow (according to ref. 22),

$$\frac{D}{u_\infty} \frac{du_e}{dx} = 4(1 - 0.416 M_{N_\infty}^2 - 0.164 M_{N_\infty}^4) \quad (63)$$

Relations (62) and (63) are plotted in figure 9 along with available data on the chordwise velocity gradient from refer-

FIGURE 9.—Chordwise-velocity-gradient parameter as function of normal Mach number component for flow at stagnation line of yawed circular cylinder.

ences 20 and 23 to 25. It is to be noted that for subsonic normal Mach numbers the experimental values of  $\frac{D}{u_\infty} \frac{du_e}{dx}$  differ somewhat from the values of equation (63). It is therefore recommended that these experimental values be used in place of the equation. The broken line in figure 9 in the region  $0.8 < M_\infty \cos \Delta < 1.5$  was drawn as an estimate of the velocity-gradient variation, since neither equation (62) nor equation (63) is strictly applicable and there are no experimental data available for that range.

#### HEAT-TRANSFER PARAMETER

For the general case of arbitrary Prandtl number and surface temperature, it is reasonable to assume from equation (51) that

$$\left[ \left( \frac{t_0 - t_w}{t_{aw} - t_w} \right) \theta'_w \right]_{Pr} = (\theta'_w)_{Pr=1} P r^{0.46} \quad (64)$$

Values of  $(\theta'_w)_{Pr=1}$  may be obtained from either table III or figure 6.

When equations (58) to (64) are combined as required,

equation (50) becomes, for the stagnation line of a yawed cylinder,

$$h_\Delta = k_w (\theta'_w)_{Pr=1} P r^{0.46} \sqrt{\frac{u_\infty}{\mu_w D} \frac{p_\infty}{R t_w} \left( \frac{p_{w_{sl}, \Delta}}{p_\infty} \right) \left( \frac{D}{u_\infty} \frac{du_e}{dx} \right)} \quad (65)$$

#### EFFECT OF YAW ANGLE AND MACH NUMBER ON HEAT-TRANSFER COEFFICIENT AT THE STAGNATION LINE

The ratio of yawed to normal heat-transfer coefficient for a given cylinder with the same conditions of free-stream and surface temperatures is, from equation (65),

$$\frac{h_\Delta}{h_{\Delta=0}} = \left( \frac{\theta'_w}{\theta'_{w_{\Delta=0}}} \right)_{Pr=1} \sqrt{\cos \Delta \frac{\left( \frac{p_{w_{sl}, \Delta}}{p_\infty} \right)}{\left( \frac{p_{w_{sl}, \Delta=0}}{p_\infty} \right)} \frac{\left( \frac{D}{u_\infty} \frac{du_e}{dx} \right)_{M_{N_\infty}}}{\left( \frac{D}{u_\infty} \frac{du_e}{dx} \right)_{M_\infty}}} \quad (66)$$

This relation is plotted in figure 10 as a function of yaw angle and Mach number for an essentially insulated surface ( $\frac{t_w}{t_0} \approx 1$ ). The value of  $\frac{D}{u_\infty} \frac{du_e}{dx}$  for these calculations was taken as the modified Newtonian value for  $M_\infty \cos \Delta > 1.5$  (eq. (62)) and from the dotted line of figure 9 for  $M_\infty \cos \Delta < 1.5$ .

For incompressible flow ( $\frac{t_0}{t_{N_0}} = 1$ ) the ratio of yawed to normal heat-transfer coefficient becomes

$$\left( \frac{h_\Delta}{h_{\Delta=0}} \right)_{M_\infty=0} = (\cos \Delta)^{\frac{1}{2}} \quad (67)$$

which is exactly that indicated experimentally for hot wires by Schubauer and Klebanoff (ref. 26). For subsonic speeds the yaw effect is very close to that for incompressible flow. The curve for  $M_\infty = 1$  is in some doubt because of the lack of suitable experimental information on the chordwise velocity gradient. The effect of yaw for supersonic flow depends on the normal component of the stream Mach number. In the region where the normal component of the stream Mach number is supersonic, the curves of the ratio of yawed to normal heat-transfer coefficient are all very close to each other and somewhat below  $\cos \Delta$  (fig. 10). As the normal Mach number becomes transonic, the ratio exceeds  $\cos \Delta$ , and at large yaw angles where the normal Mach number is subsonic, the curves tend to approach a  $(\cos \Delta)^{\frac{1}{2}}$  variation.

The influence of the exact solutions reported herein can be seen by comparing the curve for  $M_\infty = 7$  with that for the same Mach number but for  $\theta'_w$  assumed constant at the zero-yaw value. For a Mach number of infinity the ratio of yawed to normal heat-transfer coefficient (not shown in fig. 10) is only slightly below that for  $M_\infty = 7$  and from equations (58) and (66) is given by the relation

$$\left( \frac{h_\Delta}{h_{\Delta=0}} \right)_{M_\infty \rightarrow \infty} = \frac{(\theta'_w)_{t_0/t_{N_0}=sec^2 \Delta}}{(\theta'_w)_{\Delta=0}} (\cos \Delta)^{\frac{1}{2}} \quad (68)$$

The application of the results of this investigation must be terminated before the case of the parallel cylinder ( $\Delta = 90^\circ$ ), since the initial hypothesis that spanwise derivatives are identically zero does not apply.

FIGURE 10.—Effect of yaw on heat-transfer coefficient at stagnation line of circular cylinder with nearly insulated surface. Wall-temperature ratio,  $t_w/t_0$ , 1.0; Prandtl number, 1.

The effect of heating or cooling on the ratio of yawed to normal heat-transfer coefficient is shown in figure 11 for a Prandtl number of 1 in terms of a modification factor to the nearly insulated result. The factor is

$$\frac{\left(\frac{h_A}{h_{A=0}}\right)_{t_w/t_0}}{\left(\frac{h_A}{h_{A=0}}\right)_{t_w/t_0=1}} = \frac{\left(\frac{\theta'_{wA}}{\theta'_{wA=0}}\right)_{t_w/t_0}}{\left(\frac{\theta'_{wA}}{\theta'_{wA=0}}\right)_{t_w/t_0=1}} \quad (69)$$

FIGURE 11.—Effect of surface-temperature level on heat-transfer-coefficient ratio. Prandtl number, 1.

The effect of surface-temperature level from absolute zero to twice free-stream stagnation temperature on the ratio of heat-transfer coefficients is shown in figure 11 to be within  $\pm 10$  percent of the insulated heat-transfer-coefficient ratio for  $t_w/t_{N_0} < 6.5$ .

The curves of figures 10 and 11 are essentially independent of Prandtl number, since the effect of Prandtl number on

heat transfer has been approximately included through a modification to the  $Pr=1$  solutions. The effect of Prandtl number is accounted for exactly through the expression

$$\left(\frac{h_A}{h_{A=0}}\right)_{Pr=0.7} = \frac{\left[\frac{\left(\frac{t_0-t_w}{t_{aw}-t_w}\right)\theta'_{wA}}{\left(\frac{t_0-t_w}{t_{aw}-t_w}\right)\theta'_{wA=0}}\right]_{Pr=0.7}}{\left(\frac{h_A}{h_{A=0}}\right)_{Pr=1} \left(\frac{\theta'_{wA}}{\theta'_{wA=0}}\right)_{Pr=1}} \quad (70)$$

which is shown in figure 12 for  $t_w/t_0 = 0$  and 0.5. For a Prandtl number of 0.7 there is a maximum effect of approximately 4 percent, which occurs for large values of the yaw parameter and a highly cooled wall.

FIGURE 12.—Effect of Prandtl number on heat-transfer-coefficient ratio.

## SUMMARY OF RESULTS

The equations for compressible-boundary-layer development over a yawed infinite cylinder with heat transfer have been presented and solutions obtained for stagnation-line flow. The following are among the results obtained:

1. The ratio of yawed to normal heat-transfer coefficient for the stagnation line of a given cylinder varies with yaw angle  $\Lambda$  as  $(\cos \Lambda)^k$  for incompressible flow and shows nearly that variation for much of the subsonic range. Where the velocity normal to the cylinder is supersonic, this ratio is again almost a unique function of yaw angle, the ratio being in this case somewhat lower than  $\cos \Lambda$ . Most of this decrease in heat-transfer coefficient with yaw angle can be accounted for by the change in local flow quantities outside the boundary layer that occurs as the normal Mach number and strength of the bow shock change with yaw angle.

2. The effect of large amounts of heating or cooling on the ratio of yawed to normal heat-transfer coefficient is less than 10 percent for values of the yaw parameter  $t_0/t_{N_0}$  less than 6 for surface-temperature levels from absolute zero to twice free-stream stagnation temperature. Changing the Prandtl number  $Pr$  from 1 to 0.7 had at most a 4-percent effect on the ratio of yawed to normal heat-transfer coefficient.

3. The local recovery factor at the stagnation line of yawed cylinders is closely represented by  $Pr^{0.46}$ . For most purposes this may be approximated by the square root of the Prandtl number.

4. Where the independence principle does not apply, the effects of yaw on chordwise wall shear are much larger on a percentage basis than the corresponding effects on spanwise

shear or heat transfer. For yaw angles up to  $45^\circ$  and for all Mach numbers, values of a local heat-transfer parameter  $Nu/\sqrt{Re_w}$  (where  $Nu$  is Nusselt number and  $Re_w$  is the Reynolds number at the wall) for stagnation-line flow are less than 13 percent above the zero-yaw value.

5. For favorable pressure gradient, a chordwise velocity overshoot is obtained where the sum of the surface temperature and the free-stream stagnation temperature is greater than twice the external temperature ( $t_w + t_0 > 2t_{N_0}$ ). While in the unyawed case velocity overshoot is obtained only for heated surfaces, with yaw it is obtained also for cooled surfaces. Another unusual effect noted was that for Prandtl

numbers less than unity, when velocity overshoot was obtained for an insulated or cooled surface, the local stagnation enthalpy within the boundary layer exceeded the stream stagnation enthalpy.

6. The degree of secondary flow, as evidenced by the deflection of the "wall" streamline compared with the external streamline, increased with wall temperature and yaw-angle parameter.

## APPENDIX A

### SYMBOLS

$A_1, A_2, \dots$	constants in asymptotic solution	$Z$	transformed normal coordinate
$a$	sonic velocity	$z$	normal coordinate
$C$	stagnation-line chordwise velocity gradient, $C = \frac{U_e}{X} = \frac{dU_e}{dX}$	$\alpha$	streamline inclination
$C_p$	pressure coefficient, $\frac{p - p_\infty}{\frac{1}{2} \rho_\infty u_\infty^2}$	$\beta$	pressure-gradient parameter, $\frac{2m}{m+1}$
$c_f$	local skin-friction coefficient	$\gamma$	ratio of specific heats
$c_p$	specific heat at constant pressure	$\delta$	boundary-layer thickness
$D$	diameter of cylinder at stagnation line	$\zeta$	spanwise temperature-difference parameter
$f$	function related to stream function, $\psi = \sqrt{\frac{m+1}{2\nu_0 U_e X}}$	$\zeta_w$	local recovery factor
$g$	spanwise velocity variable	$\eta$	similarity variable, $Z = \sqrt{\frac{m+1}{2}} \frac{U_e}{\nu_0 X}$
$H$	total enthalpy, $c_p t + \frac{u^2 + v^2}{2}$	$\theta$	normalized enthalpy function, $\frac{H - H_w}{H_e - H_w}$
$h$	heat-transfer coefficient	$\kappa$	constant in asymptotic solution
$k$	thermal conductivity	$\Lambda$	yaw angle
$k_{su}$	Sutherland's constant	$\lambda$	$\lambda = \frac{\mu/\mu_0}{t/t_0} = \left( \frac{t_0 + k_{su}}{t_w + k_{su}} \right) \sqrt{\frac{t_w}{t_0}}$
$M$	Mach number	$\mu$	absolute viscosity
$m$	exponent from $U_e = CX^m$	$\nu$	kinematic viscosity
$Nu$	Nusselt number, $hx/k_w$	$\rho$	density
$Pr$	Prandtl number	$\tau$	wall shear stress
$p$	pressure	$\psi$	stream function
$q$	heat-transfer rate to wall per unit area	Subscripts:	
$R$	gas constant	$aw$	adiabatic wall
$\mathcal{R}$	free-stream recovery factor, $\frac{t_{aw} - t_\infty}{t_0 - t_\infty}$	$c$	chordwise
$Re_w$	Reynolds number at the wall, $\frac{\rho_w U_e X}{\mu_w}$	$e$	local flow outside boundary layer (external)
$t$	static temperature	$max$	maximum
$U$	transformed chordwise velocity component	$N$	component normal to cylinder axis
$u$	chordwise velocity component	$s$	spanwise
$v$	spanwise velocity component	$sl$	stagnation line
$W$	transformed normal velocity component	$w$	wall or surface value
$w$	normal velocity component	$\infty$	free-stream quantity ahead of bow shock wave
$X$	transformed chordwise coordinate	$0$	free-stream stagnation value
$x$	chordwise coordinate	$\Delta$	quantity pertaining to yawed cylinder
$y$	spanwise coordinate	$\Delta=0$	quantity pertaining to normal cylinder
		Superscripts:	
		$'$	differentiation with respect to $\eta$
		$\sim$	asymptotic quantity

## APPENDIX B

### SOLUTION OF ORDINARY DIFFERENTIAL EQUATIONS

Solutions to equations (25) were obtained independently at both the NACA Lewis and Langley laboratories. The solutions to equations (27) were obtained at the Langley laboratory. The procedure used at the Lewis laboratory was the forward integration technique described in appendix B of reference 27, and is based on five-point integration formulas. This is the same procedure as that used in obtaining some of the solutions presented in reference 15. An IBM card-programmed electronic calculator was used.

At the Langley laboratory the step-by-step integration procedure described in reference 28 was used. This procedure seems somewhat superior to the five-point technique and some of the results will therefore be described in detail. This particular procedure is a modification of the Runge-Kutta method and was developed primarily for automatic digital computing machines. The Bell Telephone Laboratories X-66744 relay computer at Langley is one of this type and was used for the present solutions. A step size of 0.2 was used for all the solutions, although a few solutions were also calculated with a step size of 0.1 for the purpose of evaluating the error due to step size. The calculations were carried out to  $\eta=6.0$ , since the results showed that the stream boundary conditions could always be satisfied to the desired degree of accuracy for  $\eta \leq 6.0$ .

#### CONVERGENCE TO BOUNDARY CONDITIONS

The integration of the present equations constitutes a "two-point boundary-value problem" in which the correct initial values at  $\eta=0$  (such that the boundary conditions for large  $\eta$  are satisfied) of the functions or their derivatives are usually found by a trial-and-error or interpolation method.

The procedure used to obtain convergence for the present solutions involved an adaptation of Newton's method to three variables and the idea that for large  $\eta$  the value of the functions depends on the assumed initial values at  $\eta=0$ . Applying this procedure to equations (27) with boundary conditions of equations (24) results in the following general functional forms:

$$\left. \begin{aligned} f'_\infty &= f'_w(f''_w, \theta'_w, g'_w) \\ \theta'_\infty &= \theta'_w(f''_w, \theta'_w, g'_w) \\ g'_\infty &= g'_w(f''_w, \theta'_w, g'_w) \end{aligned} \right\} \quad (B1)$$

where the subscripts  $\infty$  and  $w$  denote the computed values of the function at large  $\eta$  and at  $\eta=0$ , respectively. The error in the functions at large  $\eta$  is then given by

$$\left. \begin{aligned} df'_\infty &= \frac{\partial f'_\infty}{\partial f''_w} df''_w + \frac{\partial f'_\infty}{\partial \theta'_w} d\theta'_w + \frac{\partial f'_\infty}{\partial g'_w} dg'_w \\ d\theta'_\infty &= \frac{\partial \theta'_\infty}{\partial f''_w} df''_w + \frac{\partial \theta'_\infty}{\partial \theta'_w} d\theta'_w + \frac{\partial \theta'_\infty}{\partial g'_w} dg'_w \\ dg'_\infty &= \frac{\partial g'_\infty}{\partial f''_w} df''_w + \frac{\partial g'_\infty}{\partial \theta'_w} d\theta'_w + \frac{\partial g'_\infty}{\partial g'_w} dg'_w \end{aligned} \right\} \quad (B2)$$

The various partial derivatives in equations (B2) may be evaluated approximately from four trial solutions according to the following table:

Trial solution	Initial values			Partial derivative
	$f''_w$	$\theta'_w$	$g'_w$	
1	$f''_{w1}$	$\theta'_{w1}$	$g'_{w1}$	$\frac{\partial}{\partial f''_w}$
2	$f''_{w2}$	$\theta'_{w1}$	$g'_{w1}$	$\frac{\partial}{\partial \theta'_w}$
3	$f''_{w2}$	$\theta'_{w2}$	$g'_{w1}$	$\frac{\partial}{\partial g'_w}$
4	$f''_{w2}$	$\theta'_{w2}$	$g'_{w2}$	

The best solution of these four, for example solution 1, is then used to obtain the errors, which from equations (24) are

$$\left. \begin{aligned} df'_\infty &= f'_\infty - f'_{w1} = 1 - f'_{w1} \\ d\theta'_\infty &= \theta'_\infty - \theta'_{w1} = 1 - \theta'_{w1} \\ dg'_\infty &= g'_\infty - g'_{w1} = 1 - g'_{w1} \end{aligned} \right\} \quad (B3)$$

where  $f'_{w1}$ ,  $\theta'_{w1}$ , and  $g'_{w1}$  are the computed values at large  $\eta$  from the best solution.

Equations (B2) are then solved simultaneously for  $df'_w$ ,  $d\theta'_w$ , and  $dg'_w$ . The corrected initial values are

$$\left. \begin{aligned} f''_{w3} &= f''_{w1} + df''_w \\ \theta'_{w3} &= \theta'_{w1} + d\theta'_w \\ g'_{w3} &= g'_{w1} + dg'_w \end{aligned} \right\} \quad (B4)$$

which may be used for repeating the whole procedure until convergence is attained. In the present problem, however,

satisfactory convergence was attained by computing a trial solution with the corrected initial values and then using the results of this new solution to reevaluate  $df'_w$ ,  $d\theta'_w$ , and  $dg_w$  from equations (B3); equations (B2) were then solved for  $df''_w$ ,  $d\theta''_w$ , and  $dg''_w$  by using the partial derivatives already obtained. A new set of initial values is computed from equation (B4) and the results of the new solution, and the procedure is repeated until the boundary conditions are satisfied to the desired degree of accuracy. In most cases four or five more trial solutions were required for this purpose, which made a total of about nine trial solutions for any one case. Note, however, that in accordance with Newton's method the preceding procedure cannot be expected to give satisfactory convergence unless the errors  $df'_w$ ,  $d\theta'_w$ , and  $dg_w$  from the original four solutions are reasonably small. In the present problem these errors were limited to about 0.4 before the partial derivatives were evaluated.

#### ACCURACY OF SOLUTION

The inherent error in the Runge-Kutta method is of the order of the step size to the fifth power. A discussion of the errors in the integration procedure used here is given in reference 28.

An example of the errors due to step size and initial values for one of the present solutions is given in the following table for the case  $t_w/t_0=1.5$ ,  $t_0/t_{N_0}=1.2$ , and  $Pr=1$ :

Step size	Initial values		Boundary conditions at $\eta=6.0$	
	$f''_w$	$\theta'_w$	$f'(6.0)$	$\theta(6.0)$
0.2	1.664076	0.610859	0.999684	0.999998
.2	1.664085	.610863	.999987	.999999
.1	1.664085	.610863	.999328	1.000027

Inspection of the table indicates that the value of  $f''$  at large  $\eta$  is relatively sensitive to both the initial values and the step size. This is in accordance with the values of the partial derivatives, which for this case were

$$\frac{\partial f'_w}{\partial f''_w} = 28.4 \quad \frac{\partial f'_w}{\partial \theta''_w} = 15.4$$

$$\frac{\partial \theta_w}{\partial f''_w} = 0.51 \quad \frac{\partial \theta_w}{\partial \theta''_w} = 1.56$$

In general, all the solutions were repeated until the maximum error in the boundary conditions was at most 0.0001 in  $f'$  and 0.00001 in  $\theta$  or  $g$  at  $\eta=6.0$  with a step size of 0.2. Reducing the step size to 0.1 gives a more accurate solution, which can be used to evaluate the errors in the initial values  $f''_w$  and  $\theta'_w$  for the 0.2 step size. Thus, the sample solutions given in the table indicate that reducing the step size to 0.1, but using the same initial values, increases the errors in the outer boundary conditions by 0.00066 for  $f'(6.0)$  and by 0.00003 for  $\theta(6.0)$ . Adding these changes to the maximum allowable computing errors of 0.0001 in  $f'(6.0)$  and 0.00001 in  $\theta(6.0)$  results in an improved evaluation of the actual errors, which would be approximately 0.0007 in  $f'(6.0)$  and 0.00004 in  $\theta(6.0)$ . From these errors in  $f'$  and  $\theta$  and the values of the partial derivatives just given, the maximum errors in the initial values as obtained from equations (B2) (modified for the case of  $Pr=1$ ) are

$$df''_w = \pm 0.00001$$

$$d\theta''_w = \pm 0.00003$$

Thus, the initial values are accurate to at least the fourth decimal place, assuming that a further decrease in step size would not have much additional effect on the solutions. The functions  $f'$  and  $\theta$  are evidently accurate to the third and fourth decimal places, respectively, for large values of  $\eta$ .

#### COMPARISON OF THE TWO TECHNIQUES

Among the cases calculated, three for  $t_w/t_0=1$  were done independently by both techniques. Comparisons of values of  $f''_w$  and  $\theta'_w$  as well as values of  $f$ ,  $f'$ ,  $f''$ ,  $\theta$  and  $\theta'$  at  $\eta=4$  are given in the following tables:

$t_0/t_{N_0}$	$f''_w$		$\theta'_w$	
	Five-point	Runge-Kutta	Five-point	Runge-Kutta
1.1	1.29887	1.29886	0.57760	0.57763
1.2	1.36401	1.36400	.58446	.58447
3.0	2.40863	2.40857	.67698	.67699

$t_0/t_{N_0}$	$f(4)$		$f'(4)$		$f''(4)$		$\theta(4)$		$\theta'(4)$	
	Five-point	Runge-Kutta	Five-point	Runge-Kutta	Five-point	Runge-Kutta	Five-point	Runge-Kutta	Five-point	Runge-Kutta
1.1	3.3902	3.3901	1.0000	1.0000	0.0001	0	0.9996	0.9996	0.0016	0.0016
1.2	3.4265	3.4263	1.0002	1.0000	0	-.0001	.9997	.9996	.0015	.0015
3.0	3.8946	3.8947	1.0002	1.0001	-.0006	-.0007	.9999	.9999	.0004	.0004

There is a difference of not more than 0.0001 in the initial values and not more than 0.0002 in the functions near the outer edge of the boundary layer. An examination of other values of the functions shows them to differ by 0.0002 or

less for all values of  $\eta$ . It is felt therefore that all tabulated values in tables I, II, and III are certainly correct to three decimal places and that most of the tabulations are probably correct to  $\pm 0.0005$ .

## APPENDIX C

### ASYMPTOTIC SOLUTION

In examining the behavior of the presented solutions near the outer edge of the boundary layer, it is useful to find a solution of the system

$$f''' + ff'' = f'' - 1 - \left( \frac{t_0}{t_{N_0}} - 1 \right) (1 - g^2) - \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) (1 - \theta) \quad (27a)$$

$$g'' + fg' = 0 \quad (27b)$$

$$\theta'' + Pr f \theta' = (1 - Pr) \frac{1 - \frac{t_{N_0}}{t_0}}{1 - \frac{t_w}{t_0}} (g^2)'' \quad (27c)$$

for large  $\eta$ .

The asymptotic form for  $f$  (designated  $\tilde{f}$ ) is assumed to consist of a sum of terms, each smaller than the preceding. Only the first two terms are considered herein. The corresponding solutions for the spanwise velocity function  $\tilde{g}$  and the stagnation enthalpy function  $\tilde{\theta}$  are also obtained.

Let

$$\tilde{f} = \tilde{f}_1 + \tilde{f}_2 \quad (C1)$$

where

$$\tilde{f}_2 \ll \tilde{f}_1$$

$$\tilde{f}'_2 \ll \tilde{f}'_1$$

Since  $\lim_{N \rightarrow \infty} f' = 1$ , let

$$\tilde{f}_1 = \eta - \kappa \quad (C2)$$

where  $\kappa$  is an undetermined constant. If  $\tilde{f}_1$  is inserted into equation (27), the corresponding spanwise velocity function  $\tilde{g}_1$  and enthalpy function  $\tilde{\theta}_1$  must both be 1. Inserting equations (C1) and (C2) into equations (27) and dropping higher order terms result in

$$\tilde{f}_2''' + (\eta - \kappa) \tilde{f}_2'' = 2\tilde{f}_2' + 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) \tilde{g}_2 + \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \tilde{\theta}_2, \quad (C3)$$

$$\tilde{g}_2'' + (\eta - \kappa) \tilde{g}_2' = 0 \quad (C4)$$

$$\tilde{\theta}_2'' + Pr(\eta - \kappa) \tilde{\theta}_2' = - \frac{2(1 - Pr)}{\frac{t_w}{t_0} - 1} \left( 1 - \frac{t_{N_0}}{t_0} \right) \tilde{g}_2'' \quad (C5)$$

solution is similar to that in appendix B of reference 15. Equation (C4) can be integrated directly to give

$$\tilde{g}_2' = A_1 \exp - \frac{(\eta - \kappa)^2}{2} \quad (C6)$$

which integrates once again to the complementary error function

$$\tilde{g}_2 = -A_1 \int_{\eta}^{\infty} \exp - \frac{(\eta - \kappa)^2}{2} d\eta$$

or

$$\tilde{g}_2 = -\frac{A_1 \sqrt{\pi}}{\sqrt{2}} \operatorname{cerf} \left[ \frac{(\eta - \kappa)}{\sqrt{2}} \right] \quad (C7)$$

By use of equations (C4) and (C6), equation (C5) can now be written

$$\tilde{\theta}_2'' + Pr(\eta - \kappa) \tilde{\theta}_2' = \frac{2(1 - Pr)}{\frac{t_w}{t_0} - 1} \left( 1 - \frac{t_{N_0}}{t_0} \right) (\eta - \kappa) A_1 \exp - \frac{(\eta - \kappa)^2}{2} \quad (C8)$$

Which has as its complete solution

$$\begin{aligned} \tilde{\theta}_2 &= \frac{A_1}{\sqrt{2}} \frac{2}{\left( \frac{t_w}{t_0} - 1 \right)} \left( 1 - \frac{t_{N_0}}{t_0} \right) \frac{\sqrt{\pi}}{2} \operatorname{cerf} \left[ \frac{(\eta - \kappa)}{\sqrt{2}} \right] - \\ &\quad A_2 \sqrt{\frac{Pr}{2}} \frac{\sqrt{\pi}}{2} \operatorname{cerf} \left[ (\eta - \kappa) \sqrt{\frac{Pr}{2}} \right] \end{aligned} \quad (C9)$$

where the coefficient  $A_2$  may be evaluated by recognizing that the asymptotic forms  $\tilde{g}_2$  and  $\tilde{\theta}_2$  are identical for a Prandtl number of 1. From equations (C7) and (C9) with  $Pr = 1$ ,

$$A_2 = A_1 \left[ \frac{2 \left( 1 - \frac{t_{N_0}}{t_0} \right) + \left( \frac{t_w}{t_0} - 1 \right)}{\frac{t_w}{t_0} - 1} \right] \quad (C10)$$

Assume that this expression holds for  $Pr \neq 1$ . Equation (C9) then becomes

$$\begin{aligned} \tilde{\theta}_2 &= \frac{A_1}{\sqrt{2}} \left\{ \frac{2 \left( 1 - \frac{t_{N_0}}{t_0} \right) \sqrt{\pi}}{\frac{t_w}{t_0} - 1} \frac{1}{2} \operatorname{cerf} \left[ \frac{(\eta - \kappa)}{\sqrt{2}} \right] - \right. \\ &\quad \left. \sqrt{Pr} \left[ \frac{2 \left( 1 - \frac{t_{N_0}}{t_0} \right) + \left( \frac{t_w}{t_0} - 1 \right)}{\frac{t_w}{t_0} - 1} \right] \frac{\sqrt{\pi}}{2} \operatorname{cerf} \left[ (\eta - \kappa) \sqrt{\frac{Pr}{2}} \right] \right\} \end{aligned} \quad (C11)$$

Equations (C3), (C4), and (C5) are very similar to equations (B3) of reference 15. For  $Pr = 1$  and  $t_0/t_{N_0} = 1$ , they are identical. The procedure for obtaining the asymptotic

The expressions (C7) and (C11) for  $\tilde{g}_2$  and  $\tilde{\theta}_2$ , respectively, may now be substituted into the differential equation (C3) for  $\tilde{f}'_2$ :

$$\tilde{f}'''_2 + (\eta - \kappa) \tilde{f}''_2 - 2\tilde{f}'_2 = -A_1 \sqrt{\frac{Pr}{2}} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) \frac{\sqrt{\pi}}{2} \operatorname{cerf} \left[ (\eta - \kappa) \sqrt{\frac{Pr}{2}} \right] \right] \quad (C12)$$

For large  $\eta$  the right side of equation (C12) can be rewritten using the leading term of the following expansion of the complementary error function

$$\frac{\sqrt{\pi}}{2} \operatorname{cerf} x = \frac{e^{-x^2}}{2x} \left( 1 - \frac{1}{2x^2} + \dots \right) \quad (C13)$$

Equation (C12) then becomes

$$\tilde{f}'''_2 + (\eta - \kappa) \tilde{f}''_2 - 2\tilde{f}'_2 = -\frac{A_1}{2} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) (\eta - \kappa)^{-1} \exp \left[ -\frac{Pr}{2} (\eta - \kappa)^2 \right] \right] \quad (C14)$$

A particular solution to equation (C14) is sought wherein the leading term is of the form

$$\tilde{f}'_2 = B(\eta - \kappa)^N \exp \left[ -\frac{Pr}{2} (\eta - \kappa)^2 \right] \quad (C15)$$

Substituting equation (C15) into equation (C14) and examining the results separately for  $Pr \neq 1$  and for  $Pr = 1$  result in the following particular solutions:

For  $Pr \neq 1$

$$\tilde{f}'_{2p} = -\frac{A_1}{2Pr(Pr-1)} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) (\eta - \kappa)^{-3} \exp \left[ -\frac{Pr}{2} (\eta - \kappa)^2 \right] \right] \quad (C16)$$

and for  $Pr = 1$

$$\tilde{f}'_{2p} = \frac{A_1}{4} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) \right] (\eta - \kappa)^{-1} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] \quad (C17)$$

It is to be noted that for  $Pr < 1$ , equations (C16) and (C17) have the same qualitative behavior; that is, they are both

positive or negative depending on whether the quantity  $\left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) \right]$  is positive or negative.

The complementary function for  $\tilde{f}'_2$  can be found by noting that the homogeneous part of equation (C12) is Weber's equation. Hartree (ref. 9) gives the general solution for large values of the argument  $\eta - \kappa$ , which can be written

$$\tilde{f}'_2 = A_3(\eta - \kappa)^{-3} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] + A_4(\eta - \kappa)^2 \quad (C18)$$

In order to satisfy the boundary condition  $\lim_{\eta \rightarrow \infty} \tilde{f}'_2 = 0$ , it is necessary to take  $A_4 = 0$  in equation (C18).

The asymptotic variations of velocity and enthalpy functions are, from equations (C7), (C11), (C13), (C16), (C17), and (C18)

$$\begin{aligned} (\tilde{f}')_{Pr \neq 1} = & 1 + \frac{A_1}{2Pr(1-Pr)} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) \right] \\ & (\eta - \kappa)^{-3} \exp \left[ -\frac{Pr}{2} (\eta - \kappa)^2 \right] + \\ & A_3(\eta - \kappa)^{-3} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] \end{aligned} \quad (C19)$$

$$\begin{aligned} (\tilde{f}')_{Pr=1} = & 1 + \frac{A_1}{4} \left[ 2 \left( \frac{t_0}{t_{N_0}} - 1 \right) + \left( \frac{t_0}{t_{N_0}} \left( \frac{t_w}{t_0} - 1 \right) \right) \right] (\eta - \kappa)^{-1} \exp \\ & \left[ -\frac{(\eta - \kappa)^2}{2} \right] + A_3(\eta - \kappa)^{-3} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] \end{aligned} \quad (36)$$

$$\tilde{g} = 1 - \frac{A_1}{2} (\eta - \kappa)^{-1} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] \quad (37)$$

$$\begin{aligned} \tilde{\theta} = & 1 + A_1 \frac{\left( 1 - \frac{t_{N_0}}{t_0} \right)}{\left( \frac{t_w}{t_0} - 1 \right)} (\eta - \kappa)^{-1} \exp \left[ -\frac{(\eta - \kappa)^2}{2} \right] - \\ & \frac{A_1}{2} \left[ \frac{2 \left( 1 - \frac{t_{N_0}}{t_0} \right) + \left( \frac{t_w}{t_0} - 1 \right)}{\left( \frac{t_w}{t_0} - 1 \right)} \right] (\eta - \kappa)^{-1} \exp \left[ -\frac{Pr}{2} (\eta - \kappa)^2 \right] \end{aligned} \quad (38)$$

An examination of equations (C18) for  $Pr < 1$  and equation (36) for  $Pr = 1$  shows that the velocity functions in these cases have the same qualitative asymptotic behavior, since the  $A_1$  terms in both cases dominate over the  $A_3$  terms.

## APPENDIX D

### STAGNATION-LINE RECOVERY FACTOR FOR YAWED CYLINDER

The evaluation of the recovery factor for the stagnation line of a yawed cylinder in essentially incompressible flow is accomplished by rewriting equations (27) with the quantity  $t_{N_0}/t_0$  replaced by the equivalent expression  $1 - \frac{v_s^2}{2c_p t_0}$ , where  $\frac{v_s^2}{2c_p t_0} \ll 1$  and with  $(1 - \frac{t_w}{t_0}) \ll 1$ . The resulting equations are

$$f''' + ff'' = f'^2 - 1 \quad (D1)$$

$$g'' + fg' = 0 \quad (D2)$$

$$\theta'' + Pr f \theta' = (1 - Pr) \frac{\frac{v_s^2}{2c_p t_0}}{(1 - \frac{t_w}{t_0})} (g^2)'' \quad (D3)$$

The first two of these equations are recognized as the momentum equations for chordwise and spanwise incompressible stagnation-line flow over a yawed cylinder. The energy equation (eq. (D3)) must be further reduced by writing  $\theta$  in terms of the temperature-difference parameter

$$\xi = \frac{t - t_s}{\frac{v_s^2}{2c_p}} \quad (D4)$$

The expression for  $\theta$  in terms of  $\xi$  becomes from equations (14) and (D4)

$$\theta = 1 + \frac{(g^2 + \xi - 1) \frac{v_s^2}{2c_p}}{t_0 - t_\infty} \quad (D5)$$

Substitution of relations (D5) and (D2) into equation (D3) yields for finite  $\frac{v_s^2}{2c_p t_0}$

$$\xi'' + Pr f \xi' + 2Pr g'^2 = 0 \quad (D6)$$

Equation (D6) is identical to that of Schuh (ref. 29). With the boundary conditions:

At  $\eta = 0$

$$\xi' = 0$$

At  $\eta \rightarrow \infty$

$$\xi = 0$$

the value of  $\xi$  at the wall becomes the recovery factor and from equations (D1), (D2), and (D6) can be written

$$\xi_w = -2Pr g'_w^2 \int_0^\infty e^{-\int_0^\eta Pr f d\eta} \int_0^\eta e^{-(Pr-2) \int_0^\eta f d\eta} d\eta \quad (D7)$$

where

$$g'_w = \frac{1}{\int_0^\infty e^{-\int_0^\eta f d\eta} d\eta} \quad (D8)$$

For the present paper, values of  $\xi_w$  were obtained for  $Pr=0.7, 0.8, 0.9$ , and  $1$  and are shown in table IV. The value indicated for  $Pr=0.7$  agrees with that of Schuh.

A recovery factor for the stagnation line defined in terms of free-stream static temperature is related to  $\xi_w$  as follows:

$$\mathcal{R} \equiv \frac{t_{aw} - t_\infty}{t_0 - t_\infty} = 1 - (1 - \xi_w) \sin^2 \Lambda \quad (D9)$$
